#### Abstract

A general discussion is given of the effects of the $\alpha$-particle D-state in $(\mathrm{d}, \alpha)$ and ( $\alpha, \mathrm{d}$ ) reactions. The dependence of the cross section and of the tensor analysing powers $\mathrm{T}_{2 q}$ on the asymptotic D - to S -state ratio $\rho$ in the $\alpha$ particle and on the spectroscopic amplitudes of two-nucleon cluster transfer is discussed using a plane wave peripheral model. It is shown that the $T_{2 q}$ in $(\mathrm{d}, \alpha)$ reactions contain specific information on the $\alpha$-particle D-state and also on the coherence properties of the two-nucleon states populated.

## 1-INTRODUCTION

It is well known that the polarization observables of transfer reactions can be used to investigate the internal structure of composite particles. This property has been extensively applied to study the two and three body bound systems via the (d, p ) [1, 2], ( $\mathrm{d}, \mathrm{t}$ ) and ( $\mathrm{d},{ }^{3} \mathrm{He}$ ) [3, 4] reactions. Recently it was suggested by Santos et al. [5] that the tensor analysing powers of ( $\overrightarrow{\mathrm{d}}, \alpha$ ) reactions display the effect of a relative D-state motion of two deuteron clusters in the $\alpha$ particle. This low energy ( $\mathrm{d}, \alpha$ ) data is primarily sensitive to the parameter $D_{2}$ [1-6] which is closely related to the asymptotic $D$ to $S$-state ratio $\rho$.

The calculations of ref. [5] used a very simplified reaction model based in the plane wave approximation and did not take into account the effect of L mixing in the transition amplitude to unnatural parity states. More recently full finite range DWBA calculations [7] have shown that the tensor analysing powers
of ( $\vec{d}, \alpha$ ) reactions are specially sensitive to the $L$ mixing in unnatural parity transitions. This effect can be used to study the coherence properties of the states populated and to determine the spectroscopic amplitudes corresponding to each $L$ value. Furthermore it was realized [7, 8] that the interference between $L$ mixing and D-state effects in the presently available ( $\overrightarrow{\mathrm{d}}, \alpha$ ) tensor analysing power data makes it difficult to extract $\mathrm{D}_{2}$ from the data.

The cross section of $(\alpha, \mathrm{d})$ and $(\mathrm{d}, \alpha)$ reactions is also sensitive to the $\alpha$-particle D-state. Nagarajan and Satchler [9] have shown that the D-state effects have a J-dependence which is qualitatively in agreement with the J-dependence observed in the cross section of ${ }^{208} \mathrm{~Pb}(\alpha, \mathrm{~d})$ reactions [10]. This was previously interpreted as resulting from multistep processes [10]. To compare these two types of J-dependence we need a more complete understanding of the D-state effects in ( $\mathrm{d}, \alpha$ ) reactions and in particular a realistic estimate of $D_{2}$.

Here we develop the DWBA theory of $(\alpha, \mathrm{d})$ and $(\mathrm{d}, \alpha)$ reactions including both the S and D -state components of the $\alpha$-particle. In section 2 the decomposition of the transition amplitude for two nucleon transfer reactions is performed. These results are then applied to the particular case of ( $\alpha, \mathrm{d}$ ) and ( $\mathrm{d}, \alpha$ ) reactions in section 3 . In section 4 using a perturbative approach to generate the D -state component of the $\alpha$-particle we calculate $D_{2}$ using gaussian wave functions and realistic tensor interactions. Finally in section 5 the special sensitivity of the tensor analysing powers to the L mixing and D-state effects is studied using a peripheral model for the transfer.

## 2 - TWO NUCLEON TRANSITION AMPLITUDE

We consider a transfer reaction $\mathrm{A}(\mathrm{a}, \mathrm{b}) \mathrm{B}$ where $\mathrm{a}=\mathrm{b}+\mathrm{x}$ and $x$ is the transferred cluster. The transition amplitude for the reaction, scattering from momentum $k_{a}$ to momentum $k_{b}$ is
$\mathrm{T}=<\mathrm{B}_{\mathrm{B}} \mathrm{M}_{\mathrm{B}}, \mathrm{b} \mathrm{s}_{\mathrm{b}} \sigma_{\mathrm{b}} ; \mathbf{k}_{\mathrm{b}}|\mathrm{T}| \mathrm{AJ}_{\mathrm{A}} \mathrm{M}_{\mathrm{A}}, \mathrm{a}_{\mathrm{a}} \sigma_{\mathrm{a}} ; \mathbf{k}_{\mathrm{a}}>$
where $J_{A}, S_{a}, J_{B}, s_{b}$ are the spins of $A, \dot{a}, B, b$. Performing
an expansion into terms with definite angular momentum transfer [11] we can write

$$
\begin{gather*}
\mathrm{T}={\underset{\mathrm{s} J l}{ }\left(\mathrm{~J}_{\mathrm{A}} \mathrm{M}_{\mathrm{A}} \mathrm{~J}_{\mathrm{J}} \mid \mathrm{J}_{\mathrm{B}} \mathrm{M}_{\mathrm{B}}\right)\left(l \lambda \mathrm{~s} \sigma \mid \mathrm{J}_{\mathrm{J}}\right)}^{(-1)^{\mathrm{s}_{\mathrm{b}}-\sigma}{ }^{\mathrm{b}}\left(\mathrm{~s}_{\mathrm{a}} \sigma_{\mathrm{a}} \mathrm{~s}_{\mathrm{b}}-\sigma_{\mathrm{b}} \mid \mathrm{s} \sigma\right) \mathrm{B}_{\mathrm{s} J}^{l \lambda}}
\end{gather*}
$$

where ( $\mathrm{J}_{\mathrm{A}} \mathrm{M}_{\mathrm{A}} \mathrm{J}_{\mathrm{J}} \mid \mathrm{J}_{\mathrm{B}} \mathrm{M}_{\mathrm{B}}$ ) is the usual Clebsch-Gordan coefficient [12].

The amplitudes $\mathrm{B}_{\mathrm{sJ}}^{l \lambda}$ contain the reaction dynamics and transform under rotations like the conjugate of the spherical harmonic $\mathrm{Y}_{i}^{\lambda}$. It is important to notice that the expansion (2) in the angular momentum transfer representation is model independent since it is based only on the transformation properties under rotations of states with definite angular momentum. Therefore it does not assume any approximations regarding, for instance, spin dependent forces in the entrance and exit channels, the internal structure of the nuclei involved in the reaction and the one-step or sequential transfer nature of the reaction mechanism.

We shall now particularize eq. (2) to two-nucleon transfer. In this case $\mathrm{a}=\mathrm{b}+2$ and $\mathrm{B}=\mathrm{A}+2$. To proceed with the analysis of the transition amplitude we consider a double-parentage decomposition of the state $\mathrm{J}_{\mathrm{B}} \mathrm{M}_{\mathrm{B}}$ [13]

$$
\begin{gather*}
\mid \mathrm{B} \mathrm{~J}_{\mathrm{B}} \mathrm{M}_{\mathrm{B}}>=\underset{\eta \mathrm{A}^{\prime} \mathrm{JM}_{J}}{\sum_{\mathrm{J}}} \delta^{\delta_{\mathrm{J}}(\eta)\left|\eta \mathrm{JM}_{\mathrm{J}}>\right| \mathrm{A}^{\prime} \mathrm{J}_{\mathrm{A}^{\prime}} \mathrm{M}_{\mathrm{A}^{\prime}}>}  \tag{3}\\
\left(\mathrm{J}_{\mathrm{A}^{\prime}} \mathrm{M}_{\mathrm{A}^{\prime}} \mathrm{J} \mathrm{M}_{\mathrm{J}} \mid \mathrm{J}_{\mathrm{B}} \mathrm{M}_{\mathrm{B}}\right)
\end{gather*}
$$

where $\mathcal{S}_{J}(\eta)$ is the spectroscopic amplitude for the $\eta, \mathrm{J}$ configuration of the two nucleons with total angular momentum J relative to the state $\mathrm{J}_{\mathrm{A}^{\prime}} \mathrm{M}_{\mathrm{A}^{\prime}}$. The state $\mid \eta \mathrm{J} \mathrm{M}_{\mathrm{J}}>$ results from coupling two single particle states with angular momenta $\mathrm{j}_{1}, \mathrm{j}_{2}$ which are abbreviated by the parameter $\eta$. By transforming from $\mathrm{j}-\mathrm{j}$ to $\mathrm{L}-\mathrm{s}$ coupling we can write

$$
\begin{align*}
& \mid \eta\left(\mathrm{j}_{1} \mathrm{j}_{2}\right) \mathrm{JM}_{\mathrm{J}}>=  \tag{4}\\
& \sum_{\mathrm{LMs}_{\mathrm{x}}{ }^{\mathrm{G}}} \mathcal{G}_{\mathrm{Ls}}^{\mathrm{x}}{ }_{\mathrm{x}} \mathrm{~J}(\eta)\left|l_{1} l_{2}, \mathrm{LM}>\right| \mathrm{s}_{\mathrm{x}} \sigma_{\mathrm{x}}>\left(\mathrm{L} \mathrm{M} \mathrm{~s}_{\mathrm{x}} \sigma_{\mathrm{x}} \mid \mathrm{J} \mathrm{M}_{\mathrm{J}}\right) .
\end{align*}
$$

Here $\mathcal{G}_{\mathrm{Ls}}^{\mathrm{x}}{ }_{J}(\eta)$ are the usual symmetrized [13] Ls - jj recoupling
coefficients and $\left|S_{x} \sigma_{x}\right\rangle$ is a spin-only wave function for the two nucleons with total spin $s_{x}$. The dependence on the position coordinates $\mathbf{r}_{1}$ and $\mathbf{r}_{2}$ of the two nucleons relative to A (Fig. 1) is contained in $\left|l_{1} l_{2}, \mathrm{LM}\right\rangle$.

Fig. 1-Coordinate vectors for a $\mathrm{A}(\alpha, \mathrm{d}) \mathrm{B}$ reaction.

It is now assumed that there is no exchange of nucleons between particles in the entrance and exit channels, no excitation of the target and no reorientation of the target spin through spin-dependent forces. With this assumption the integration over the target internal coordinates selects from eq. (3) the term $\mathrm{A}^{\prime}=\mathrm{A}$ in which the target is in its ground state. Putting eqs. (3) and (4) into eq. (1), performing the integration over the internal coordinates
of $A$ and writing the resulting expression in the form of eq. (2) we find that

$$
\begin{equation*}
\mathrm{B}_{\mathrm{sJ}}^{l \lambda}=\sum_{\eta \mathrm{s}_{\mathrm{x}} \mathrm{~L}} \mathcal{S}_{\mathrm{J}}(\eta) \mathcal{G}_{\mathrm{L} \mathrm{~s}_{\mathrm{x}} \mathrm{~J}}(\eta) \sum_{\mathrm{L}^{\prime}} \mathrm{A}_{l \mathrm{sJ} \mathrm{~s}_{\mathrm{x}}}^{\mathrm{LL}{ }^{\prime}} \beta_{\mathrm{s}_{\mathrm{x}} \mathrm{~L}^{\prime} \mathrm{L}}^{l \lambda} \tag{5}
\end{equation*}
$$

The coefficients $\mathrm{A}_{\text {lsJs }}^{\mathrm{LL} \prime}$ are the same as in ref. [14] and are given by

$$
\begin{equation*}
\mathrm{A}_{l \mathrm{sJs}}^{\mathrm{x}} \mathrm{LL}^{\prime}=\hat{\mathrm{s}}_{\mathrm{a}} \hat{l}(-1)^{\mathrm{J}-\mathrm{s}-l-\mathrm{L}^{\prime}} \mathrm{W}\left(\mathrm{~L} \mathrm{~s}_{\mathrm{x}} l \mathrm{~s} ; \mathrm{J} \mathrm{~L}^{\prime}\right) \tag{6}
\end{equation*}
$$

while

$$
\begin{align*}
& \beta_{\mathrm{s}_{\mathrm{x}}}^{\mathrm{L}^{\prime} \mathrm{L}}=\frac{\mathrm{L}^{\prime 2}}{\hat{\mathrm{~S}}_{\mathrm{a}} \hat{\mathrm{~S}}} \sum_{\sigma_{\mathrm{x}} \sigma_{\mathrm{a}} \sigma_{\mathrm{b}}}(-1)^{\mathrm{M}^{\prime}}\left(\mathrm{L} \mathrm{M} \mathrm{~L}^{\prime}-\mathrm{M}^{\prime} \mid l \lambda\right)(-1)^{\mathrm{s}^{-\sigma}{ }_{\mathrm{b}}} \\
& \sigma \mathrm{MM}^{\prime} \quad\left(\mathrm{S}_{\mathrm{a}} \sigma_{\mathrm{a}} \mathrm{~S}_{\mathrm{b}}-\sigma_{\mathrm{b}} \mid \mathrm{S} \sigma\right) \quad\left(\mathrm{L}^{\prime} \mathrm{M}^{\prime} \mathrm{S}_{\mathrm{x}} \sigma_{\mathrm{x}} \mid \mathrm{S} \sigma\right)  \tag{7}\\
& <\mathrm{b} \mathrm{~s}_{\mathrm{b}} \sigma_{\mathrm{b}} ; \mathrm{s}_{\mathrm{x}} \sigma_{\mathrm{x}} ; l_{1} l_{2} \mathrm{~L} \mathrm{M} ; \mathbf{k}_{\mathrm{b}}|\mathrm{~T}| \mathrm{a}_{\mathrm{a}} \sigma_{\mathrm{a}} ; \mathbf{k}_{\mathrm{a}}>\text {. }
\end{align*}
$$

Here $(2 \mathrm{~s}+1)^{1 / 2}$ is abbreviated by $\hat{\mathrm{s}}$. We notice that the total orbital angular momentum transfer in the reaction, $l$, is composed of a part $L$ and a part $L^{\prime}$ which in turn results from the decomposition of the spin transfer $s$ into a spin part $s_{x}$ and an orbital part L'.

In the microscopic approach to two-nucleon transfer reactions the amplitudes $\beta_{\mathrm{s}_{\mathrm{x}} \mathrm{L}^{\prime} \mathrm{L}}^{l \lambda}$ are calculated from states $\mid l_{1} l_{2} \mathrm{LM}>$ constructed from shell model wave functions in the nucleon coordinates $\mathbf{r}_{1}$ and $\mathbf{r}_{2}$. However to obtain the projectile form factor it is convenient to transform from the coordinates $\mathbf{r}_{1}$ and $\mathbf{r}_{2}$ to $\mathbf{r}_{12}=\mathbf{r}_{1}-\mathbf{r}_{2}$ and $\mathbf{R}=\left(\mathbf{r}_{1}+\mathbf{r}_{2}\right) / 2$. These vectors are represented schematically in Fig. 1. Using a basis of normalized wave functions $\phi_{\mathrm{n} l}$ we can perform the expansion

$$
\begin{equation*}
<\mathbf{r}_{1} \mathbf{r}_{2} \mid l_{1} l_{2} \mathrm{~L} M>=\sum_{\mathrm{n} l_{\mathrm{x} \Lambda}} \mathrm{c}_{\mathrm{n} l_{\mathrm{x}} \mathrm{NA}}(\eta)\left[\phi_{\mathrm{n} l_{\mathrm{x}}}\left(\mathbf{r}_{12}\right) \otimes \phi_{\mathrm{NA}}(\mathbf{R})\right]_{\mathrm{L}}^{\mathrm{M}} \tag{8}
\end{equation*}
$$

where n and N are quantum numbers that specify the number of nodes of the wave functions $\phi$. In the particular case of harmonic oscillator wave functions the $c_{n l_{x} N_{\Lambda}}$ are the well known Moshinsky coefficients [15].

We now assume that the reaction is a one-step process and take $\mathrm{V}_{\mathrm{bx}}$ for the transfer interaction. It is then straightforward to conclude that the T amplitude in eq. (7) depends on the internal structure of the projectile through the matrix element $<\mathrm{bs}_{\mathrm{b}} \sigma_{\mathrm{b}} ; \mathrm{nj}_{\mathrm{x}} \mathrm{m}_{\mathrm{x}}\left|\mathrm{V}_{\mathrm{bx}}\right| \mathrm{as}_{\mathrm{a}} \sigma_{\mathrm{a}}>$. Here $\mathrm{j}_{\mathrm{x}}=\mathrm{I}_{\mathrm{x}}+\mathbf{s}_{\mathrm{x}}$ is the total angular momentum of the transferred two-nucleon cluster.

To proceed with the analysis of the transition matrix elements we use the DWBA theory. No spin dependent interactions either in the entrance or the exit channel are considered in order to simplify the discussion. With this assumption the DWBA amplitude in eq. (7) is [14]

$$
\begin{align*}
& <\mathrm{b} \mathrm{~s}_{\mathrm{b}} \sigma_{\mathrm{b}} ; \mathrm{s}_{\mathrm{x}} \sigma_{\mathrm{x}} ; l_{1} l_{2} \mathrm{~L} \mathrm{M} ; \mathbf{k}_{\mathrm{b}}|\mathrm{~T}| \mathrm{as}_{\mathrm{a}} \sigma_{\mathrm{a}} ; \mathbf{k}_{\mathrm{a}}>= \\
& \underset{\mathrm{nN} \Lambda \xi}{\Sigma} \mathrm{c}_{\mathrm{n} l \mathrm{x} N \Lambda}(\eta)\left(l_{\mathrm{x}} \lambda_{\mathrm{x}} \Lambda \xi \mid \mathrm{LM}\right)\left(l_{\mathrm{x}} \lambda_{\mathrm{x}} \mathrm{~S}_{\mathrm{x}} \sigma_{\mathrm{x}} \mid \mathrm{j}_{\mathrm{x}} \mathrm{~m}_{\mathrm{x}}\right) \tag{9}
\end{align*}
$$

$$
\begin{aligned}
& <\mathrm{bs}_{\mathrm{b}} \sigma_{\mathrm{b}} ; \mathrm{x}\left(\mathrm{n} l_{\mathrm{x}} \mathrm{~s}_{\mathrm{x}}\right) \mathrm{j}_{\mathrm{x}} \mathrm{~m}_{\mathrm{x}}\left|\mathrm{~V}_{\mathrm{bx}}\right| \mathrm{as}_{\mathrm{a}} \sigma_{\mathrm{a}}>\chi_{\mathrm{a}}^{(+)}\left(\mathrm{k}_{\mathrm{a}}, \mathrm{r}_{\mathrm{a}}\right) .
\end{aligned}
$$

Here $\chi_{\mathrm{a}}$ and $\chi_{\mathrm{b}}$ are distorted waves and r is the displacement vector between the centers of mass of the two-nucleon clusters $x$ and $b$.

$$
3-(\alpha, \mathrm{d}) \text { AND }(\mathrm{d}, \alpha) \text { REACTIONS }
$$

Our present interest is to consider the particular case of ( $\alpha, \mathrm{d}$ ) reactions. The range of $\mathrm{n}, l_{\mathrm{x}}, \mathrm{s}_{\mathrm{x}}$ values to be considered in eqs. (5), (7) and (9) depends on the assumptions that are made regarding the wave functions of the $\alpha$-particle and residual nucleus. Conservation of isospin implies that the transferred two-nucleon cluster has $T=0$. Thus it must be either an even parity state with $\mathrm{s}_{\mathrm{x}}=1$ or an odd parity state with $\mathrm{s}_{\mathrm{x}}=0$. The contribution from the latter type of state is believed to be small since it can only arise from the overlap with odd parity components in the variable $\mathbf{r}_{12}$ in the $\alpha$ particle.

It is therefore usually assumed that the transferred two-nucleon cluster has even parity and only the $l_{\mathrm{x}}=0$ state is taken into

## F. D. SANTos et al. - D-state and nuclear structure effects in ( $d, \alpha$ ) reactions

account in DWBA calculations. Furthermore it is frequently supposed that the two nucleons are in a relative $S$ state with no nodes $(\mathrm{n}=0)$. However we note that the $l_{\mathrm{x}}=2$ states have a non-vanishing overlap with parts of the $\alpha$ particle wave function and in particular with its D-state component.

With $l_{\mathrm{x}}=0$ we conclude that $\mathrm{j}_{\mathrm{x}}=1$ and the $\mathrm{V}_{\mathrm{dx}}$ matrix element of eq (9) can be expanded as [7]

$$
\begin{align*}
& <\mathrm{d} 1 \sigma_{\mathrm{d}} ; \mathrm{x}(\mathrm{n} 01) 1 \sigma_{\mathrm{x}}\left|\mathrm{~V}_{\mathrm{dx}}\right| \alpha>= \\
& 1 / 2 \sum_{\mathrm{L}^{\prime}=0,2}(-1)^{\sigma_{\mathrm{d}}}\left(\mathrm{~L}^{\prime} \mathrm{M}^{\prime} 1 \sigma_{\mathrm{x}} \mid 1-\sigma_{\mathrm{d}}\right) \mathrm{v}_{\mathrm{nL} L^{\prime}}(\mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathrm{r}}) \tag{10}
\end{align*}
$$

The vector $r$ represented in Fig. 1 is the separation between the centers of mass of the clusters; $\mathbf{r}=\left(\mathbf{r}_{32}+\mathbf{r}_{41}\right) / 2$ with $\mathbf{r}_{\mathbf{i j}}=\mathbf{r}_{\mathbf{i}}-\mathbf{r}_{j}$. As before we denote by 1,2 the transferred nucleons and by 1,3 and 2,4 the identical particles in the $\alpha$ particle. Conservation of parity implies that $\mathrm{L}^{\prime}$ can only be 0 and 2 . The $\mathrm{L}^{\prime}=0$ and $\mathrm{L}^{\prime}=2$ terms on the right hand side of eq. (10) correspond to two different spin configurations in the $\alpha$ particle in which the spins of the two spin one clusters are antiparallel and parallel, respectively. When substituting eqs. (9) and (10) into eq. (7) and performing the summations over magnetic quantum numbers it is found that the orbital angular momentum $\mathrm{L}^{\prime}$ in eq. (10) is in fact the same as $L^{\prime}$ in eq. (7). This gives

$$
\begin{equation*}
\beta_{1 \mathrm{~L}^{\prime} \mathrm{L}}^{l \lambda}={\underset{\mathrm{nN}}{ }} \mathrm{c}_{\mathrm{n} 0 \mathrm{NL}}(\eta) \tilde{\mathrm{B}}_{\mathrm{nNLL}} \mathrm{lN}^{\prime \lambda}, \tag{11}
\end{equation*}
$$

with

$$
\begin{align*}
& \tilde{\mathrm{B}}_{\mathrm{nNLL}}^{l \lambda}= \sqrt{3} / 2 \underset{\mathrm{MM}^{\prime}}{\Sigma}(-1)^{1+\mathrm{M}^{\prime}}\left(\mathrm{LM} \mathrm{~L}^{\prime}-\mathrm{M}^{\prime} \mid l \lambda\right) \\
& \int \mathrm{d}^{3} \mathrm{R} \int \mathrm{~d}^{3} \mathrm{r} \chi_{\mathrm{d}}^{(-)^{*}}\left(\mathbf{k}_{\mathrm{d}}, \mathbf{r}_{\mathrm{d}}\right) \phi_{\mathrm{NL}}(\mathrm{R}) \mathrm{Y}_{\mathrm{L}}^{\mathrm{M}^{*}}(\hat{\mathbf{R}})  \tag{12}\\
& \mathrm{v}_{\mathrm{nL}^{\prime}}(\mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathbf{r}}) \chi_{\alpha}^{(+)}\left(\mathbf{k}_{\alpha}, \mathbf{r}_{\alpha}\right)
\end{align*}
$$

Using eqs. (5) and (11) we can write

$$
\begin{equation*}
\mathrm{B}_{1 J}^{l \lambda}=\sum_{\mathrm{nNL}} \mathrm{G}_{\mathrm{nNLJ}} \sum_{\mathrm{L}^{\prime}} \mathrm{A}_{\mathrm{LiJJ}}^{\mathrm{LL}} \tilde{\mathrm{~B}}_{\mathrm{nNLL}}{ }^{l \lambda} \tag{13}
\end{equation*}
$$

Portgal. Phys. - Vol. 15, fasc. 1-2, pp. 65-88, 1984

## F. D. Santos et al. - D-state and nuclear structure effects in ( $d, \alpha$ ) reactions

Here the information on the nuclear structure of the $\mathrm{A}+2$ nucleus is as much as possible concentrated in the amplitude

$$
\begin{equation*}
\mathrm{G}_{\mathrm{nNLJ}}=\sum_{\eta} \mathscr{S}_{J}(\eta) \mathcal{S}_{\mathrm{L} 1 J}(\eta) \mathrm{c}_{\mathrm{nONL}}(\eta) . \tag{14}
\end{equation*}
$$

On the other hand the information on the $\alpha$ particle is contained in the sum over $\mathrm{L}^{\prime}$.

The differential cross section for the $\mathrm{A}(\alpha, \mathrm{d}) \mathrm{B}$ reaction is an incoherent sum over $l$ and J

$$
\begin{align*}
\mathrm{d} \sigma / \mathrm{d} \Omega & \propto \sum_{J l \lambda}\left(2 \mathrm{~J}_{\mathrm{B}}+1\right) /(2 l+1)\left|\mathrm{B}_{1 J}^{l \lambda}\right|^{2}  \tag{15}\\
& =\sum_{J l \lambda}\left(2 \mathrm{~J}_{\mathrm{B}}+1\right) /\left.(2 l+1) \sum_{\mathrm{nNL}}^{\sum} \mathrm{G}_{\mathrm{nNLJ}} \sum_{\mathrm{L}^{\prime}} \mathrm{A}_{l 1 J^{2}}^{L L J^{\prime}} \tilde{\mathrm{B}}_{\mathrm{nNLL}}^{l \lambda}\right|^{2} .
\end{align*}
$$

With the inclusion of the $\alpha$-particle D -state the total orbital angular momentum transfer $l$ may not be equal to L. Furthermore we notice that the $\mathrm{L}^{\prime}=2$ contribution introduces a J dependence into the cross section through the $\mathrm{A}_{i 1 \mathrm{I}_{1}}^{\mathrm{LL}}$ coefficients.

Here we are particularly interested in the analysing powers of the inverse reaction $B(\vec{d}, \alpha) A$. From invariance under time reversal the analysing powers $\mathrm{T}_{\mathrm{kq}}$ of the $\mathrm{B}(\overrightarrow{\mathrm{d}}, \alpha) \mathrm{A}$ reaction are related with the polarization tensors $\mathrm{t}_{\mathrm{kq}}$ of the $\mathrm{A}(\alpha, \overrightarrow{\mathrm{d}}) \mathrm{B}$ reaction by [11]

$$
\begin{equation*}
\mathrm{T}_{\mathrm{kq}}=(-1)^{\mathrm{k}} \mathrm{t}_{\mathrm{kq}} \tag{16}
\end{equation*}
$$

when using the same coordinate system on both sides of eq. (16). The polarization tensors $t_{\mathrm{kq}}$ are given by

$$
\begin{equation*}
\mathrm{t}_{\mathrm{kq}}=\operatorname{Trace}\left(\mathrm{T}^{\dagger} \tau_{\mathrm{kq}}(1) \mathrm{T}\right) / \operatorname{Trace}\left(\mathrm{T}^{\dagger} \mathrm{T}\right) \tag{17}
\end{equation*}
$$

where T is the transition amplitude for the ( $\alpha, \mathrm{d}$ ) reaction and $\tau_{\mathrm{kq}}(1)$ are the usual spin one operators [16]. Using eqs. (2), (16) and (17) we obtain

$$
\begin{align*}
& \mathrm{T}_{\mathrm{kq}}=-\sqrt{3}\left(\sum_{l \lambda}(2 l+1)^{-1}\left|\mathrm{~B}_{1 J}^{l \lambda}\right|^{2}\right)^{-1} \\
& \sum_{J l \lambda^{\prime} l^{\prime} \lambda^{\prime}}^{\sum}(-1)^{\mathrm{k}+J+\lambda} \mathrm{W}\left(1 l 1 l^{\prime} ; \mathrm{Jk}\right)\left(l-\lambda l^{\prime} \lambda^{\prime} \mid \mathrm{kq}\right) \mathrm{B}_{1 J}^{l \lambda} \mathrm{~B}_{\left.1 S^{\prime \lambda}\right]^{*}}^{*} . \tag{18}
\end{align*}
$$

Unlike the cross section the $\mathrm{T}_{\mathrm{kq}}$ involve a coherent sum over $\mathrm{B}_{15}^{l \lambda}$ amplitudes with different $l$.

## 4 - THE ASYMPTOTIC D- to S-STATE RATIO <br> IN THE $\alpha$ PARTICLE

A full finite range DWBA calculation for $B(\vec{d}, \alpha) A$ reactions requires the knowledge of the radial wave functions $\mathrm{v}_{\mathrm{nL} L^{\prime}}(\mathrm{r})$, defined in eq. (10). We consider only the $\mathrm{V}_{\mathrm{dx}}$ matrix element for $\mathrm{n}=0$ because the dominant component of the expansion (8) in the internal variable $r_{12}$ of the transferred cluster is an $S$ state with no nodes [17]. In the following it is therefore assumed that $\mathrm{n}=0$ and all dependence on n is dropped. However we note that at least in the $L^{\prime}=0$ part of the transition amplitude the contributions from S state cluster states with $\mathrm{n} \neq 0$ are not negligible for some cases [18].

The overlap between the $\alpha$ particle wave function and the two spin-one clusters has an expansion analogous to eq. $(10)[5,7]$

$$
\begin{align*}
& <\phi_{\mathrm{d}}^{\sigma_{\mathrm{d}}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2) \mid \phi_{\alpha}>=  \tag{19}\\
& \quad 1 / 2 \sum_{\mathrm{L}^{\prime}=0,2}(-1)^{\sigma_{\mathrm{d}}}\left(\mathrm{~L}^{\prime} \mathrm{M}^{\prime} 1 \sigma_{\mathrm{x}} \mid 1-\sigma_{\mathrm{d}}\right) \mathrm{u}_{\mathrm{L}^{\prime}}(\mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathrm{r}})
\end{align*}
$$

This function satisfies the equation

$$
\begin{array}{r}
-\left(\mathrm{B}_{\alpha}-\mathrm{B}_{\mathrm{d}}-\mathrm{B}_{\mathrm{x}}+\mathrm{T}_{\mathrm{r}}\right)<\phi_{\mathrm{d}}^{\sigma_{\mathrm{d}}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2) \mid \phi_{\alpha}>  \tag{20}\\
=<\phi_{\mathrm{d}}^{\sigma_{\mathrm{d}}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2)\left|\mathrm{V}_{\mathrm{dx}}\right| \phi_{\alpha}>
\end{array}
$$

where on the right hand side the matrix element is the same as in eq. (10). $\mathrm{B}_{a}, \mathrm{~B}_{\mathrm{d}}, \mathrm{B}_{\mathrm{x}}$ are binding energies and $\mathrm{T}_{\mathrm{r}}$ is the kinetic energy in $\mathbf{r}$. Combining eqs. (10), (19) and (20) we conclude that the radial wave functions $u_{L^{\prime}}$ and $v_{L^{\prime}}$ are related by

$$
\begin{equation*}
\mathrm{v}_{\mathrm{L}^{\prime}}(\mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathbf{r}})=-\left(\hbar^{2} / 2 \mathrm{M}\right)\left(\alpha^{2}-\nabla^{2}\right) \mathrm{u}_{\mathrm{L}^{\prime}}(\mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathbf{r}}) \tag{21}
\end{equation*}
$$

where $\alpha=\left[2 \mathrm{M}\left(\mathrm{B}_{\alpha}-\mathrm{B}_{\mathrm{d}}-\mathrm{B}_{\mathrm{x}}\right) / \hbar^{2}\right]^{1 / 2}$ is the wave number of the relative motion between clusters in the $\alpha$ particle. Eq. (21) shows that asymptotically, for large $r$,

$$
\begin{equation*}
\mathrm{u}_{\mathrm{L}^{\prime}}(\mathrm{r}) \underset{\mathrm{r} \rightarrow \infty}{\longrightarrow} n_{L^{\prime}} \mathrm{i}^{L^{\prime}} \mathrm{h}_{\mathrm{L}^{\prime}}(\mathrm{i} \alpha \mathrm{r}) \tag{22}
\end{equation*}
$$

F. D. Santos et al. - D-state and nuclear structure effects in ( $d, \alpha$ ) reactions
neglecting the Coulomb interaction between clusters. The asymptotic D - to S -state ratio in the $\alpha$ particle is [5]

$$
\begin{equation*}
\rho=n_{2} / n_{0} . \tag{23}
\end{equation*}
$$

In low energy ( $\mathrm{d}, \alpha$ ) reactions the DWBA calculations are not very sensitive to the precise and presently unknown short range behaviour of the functions $u_{L^{\prime}}(r)[7,8]$. The calculated tensor analyzing powers depend to a good approximation upon $\mathrm{u}_{0}$ and $\mathrm{u}_{2}$ only through the parameter $\mathrm{D}_{2}$ defined by [1]

$$
\begin{equation*}
\mathrm{D}_{2}=\int_{0}^{\infty} \mathrm{u}_{2}(\mathrm{r}) \mathrm{r}^{4} \mathrm{dr} / 15 \int_{0}^{\infty} \mathrm{u}_{0}(\mathrm{r}) \mathrm{r}^{2} \mathrm{dr} \tag{24}
\end{equation*}
$$

An alternative expression

$$
\begin{equation*}
\mathrm{D}_{2}=\left(2 \mathrm{M} / \hbar^{2} \alpha^{2}\right) \quad \int_{0}^{\infty} \mathrm{V}_{2}(\mathrm{r}) \mathrm{r}^{4} \mathrm{dr} / \int_{0}^{\infty} \mathrm{u}_{0}(\mathrm{r}) \mathrm{r}^{2} \mathrm{dr} \tag{25}
\end{equation*}
$$

is obtained using eq. (21) to relate the coefficients of the $\mathrm{k}^{2}$ term in a power series expansion of $\mathrm{u}_{2}$ and $\mathrm{v}_{2}$ in momentum space. The substitution of the asymptotic forms (22) into eq. (24) gives the well known relation [ 1,19 ]

$$
\begin{equation*}
\mathrm{D}_{2} \simeq \rho / \alpha^{2} . \tag{26}
\end{equation*}
$$

However the reliability of this approximate relation is expected to be much smaller in ( $\mathrm{d}, \alpha$ ) reactions than in ( $\mathrm{d}, \mathrm{p}$ ) reactions because of the large $\alpha$ particle binding energy.

A non-vanishing $D_{2}$ can only be obtained through the nucleon-nucleon tensor interaction in the four body bound system. To obtain an estimate of $\mathrm{D}_{2}$ we assume, in analogy with what is presently known about the three body bound system [3], that $\mathrm{u}_{0}$ and $\mathrm{u}_{2}$ are primarily determined, respectively, by the overlaps $<\phi_{\mathrm{d}}(3,4) \phi_{\mathrm{x}}(1,2) \mid \phi_{a \mathrm{~S}}>$ and $<\phi_{\mathrm{d}}(3,4) \phi_{\mathrm{x}}(1,2) \mid \phi_{a \mathrm{D}}>$ with the S and D state components of the $\alpha$ particle wave function

$$
\begin{equation*}
\phi_{\alpha}=\phi_{\alpha \mathrm{S}}+\phi_{a \mathrm{D}} \tag{27}
\end{equation*}
$$

It is important to emphasize that this is an approximation. For instance it is easily verified that the $S$ state component $\phi_{\alpha S}$ gives
contributions to $\mathrm{u}_{2}$ through the D -states in the spin one clusters. These contributions are probably small because they arise from low probability components in $\phi_{\alpha S}$ that result from coupling states with non-zero orbital angular momenta in the coordinates $\mathbf{r}_{12}, \mathbf{r}_{34}, \mathbf{r}$ to a total $\mathrm{L}^{\prime}=0$.

A model to generate $\phi_{a \mathrm{D}}$ is required in order to calculate $\mathrm{D}_{2}$. Using a perturbative treatment [5] we can write, to first order in the tensor interaction,

$$
\begin{equation*}
\left(T+\sum_{i<j} V_{c}(i, j)+B_{\alpha}\right)\left|\phi_{a D}>\simeq-\sum_{i<j} V_{T}(i, j)\right| \phi_{a S}> \tag{28}
\end{equation*}
$$

Here $\mathrm{V}_{\mathrm{c}}(\mathrm{i}, \mathrm{j})$ and

$$
\begin{equation*}
V_{T}(i, j)=V_{T}\left(r_{i j}\right) S_{12}(i, j) \tag{29}
\end{equation*}
$$

are the central and tensor parts of the nucleon-nucleon interaction. The overlap of eq. (28) with the spin one clusters satisfies the equation

$$
\begin{align*}
\left(\mathrm{B}_{\alpha}-\mathrm{B}_{\mathrm{d}}-\mathrm{B}_{\mathrm{x}}\right. & \left.+\mathrm{T}_{\mathrm{r}}\right)<\phi_{\mathrm{d}}^{\sigma_{\mathrm{d}}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2) \mid \phi_{\alpha \mathrm{D}}>\simeq  \tag{30}\\
& -<\phi_{\mathrm{d}}^{\sigma_{\mathrm{d}}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2)\left|\sum_{\mathrm{i}<\mathrm{j}} \mathrm{~V}_{\mathrm{T}}(\mathrm{i}, \mathrm{j})\right| \phi_{\alpha \mathrm{S}}>
\end{align*}
$$

if the central interactions between clusters are neglected. This approximation is based on the fact that the effect of $\mathrm{V}_{\mathrm{c}}$ is reduced by the centrifugal barrier associated with the D-state in $\mathbf{r}$.

On the right hand side of eq. (30) there are no contributions from $V_{T}(1,3)$ and $V_{T}(2,4)$ since the nucleon pairs 1,3 and 2,4 are in singlet states. Furthermore the tensor interactions $\mathrm{V}_{\mathrm{T}}(1,2)$ and $\mathrm{V}_{\mathrm{T}}(3,4)$ do not generate a relative D -state motion of the cluster if we consider only the dominant component of $\phi_{\alpha S}$ exclusively with $S$ states in $\mathbf{r}_{12}, \mathbf{r}_{34}, \mathbf{r}$. Thus combining eqs. (10), (21) and (30) yields

$$
\begin{gather*}
<\phi_{\mathrm{d}}^{\sigma_{\mathrm{d}}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2)\left|\mathrm{V}_{\mathrm{T}}(2,3)+\mathrm{V}_{\mathrm{T}}(1,4)\right| \phi_{\alpha \mathrm{S}}>= \\
1 / 2(-1)^{\sigma_{\mathrm{d}}}\left(2 \mathrm{M}^{\prime} 1 \sigma_{\mathrm{x}} \mid 1-\sigma_{\mathrm{d}}\right) \mathrm{V}_{2}(\mathrm{r}) \mathrm{Y}_{2}^{\mathrm{M}^{\prime}}(\hat{\mathrm{r}}) \tag{31}
\end{gather*}
$$

Portgal. Phys. - Vol. 15, fasc. 1-2, pp. 65-88, 1984
F. D. Santos et al. -D-state and nuclear structure effects in ( $d, \alpha$ ) reactions

Using eqs. (19), (25) and (31) it is now straightforward to calculate the parameter $\mathrm{D}_{2}$. This calculation is considerably simplified by the use of gaussian wave functions to represent the bound states
$\phi_{a S}=\mathrm{E}(\lambda) \exp \left[-\lambda\left(r_{12}^{2}+\mathrm{r}_{34}^{2}+2 \mathrm{r}^{2}\right) / 4\right] \chi_{0}(1,3) \chi_{0}(2,4)$,
$\phi_{\mathrm{d}}^{\boldsymbol{\sigma}}(3,4) \phi_{\mathrm{x}}^{\sigma_{\mathrm{x}}}(1,2)=\mathrm{F}^{2}(\nu) \exp \left[-\nu\left(\mathrm{r}_{34}^{2}+\mathrm{r}_{12}^{2}\right) / 2\right]$

$$
\begin{equation*}
\chi_{1}^{\sigma_{\mathrm{d}}}(3,4) \chi_{1}^{\sigma_{\mathrm{x}}}(1,2) \tag{33}
\end{equation*}
$$

In eq. (33) we made the usual assumption of describing $x$ by a deuteron wave function. $E(\lambda)=2^{-3 / 2}(\lambda / \pi)^{9 / 4}$ and $\mathrm{F}(\nu)=(\nu / \pi)^{3 / 4}$ are normalization constants and $\chi_{0}(\mathrm{i}, \mathrm{j})$ and $\chi_{1}^{\sigma}(\mathrm{i}, \mathrm{j})$ are singlet and triplet spin wave functions. The parameters $\lambda$ and $\nu$ are related to the $\alpha$-particle and deuteron rms radius by

$$
\begin{align*}
& <\mathrm{r}^{2}>_{\alpha \text { particle }}^{1 / 2}=3 /(2 \sqrt{2 \lambda}),  \tag{34}\\
& <\mathrm{r}^{2}>_{\text {deuteron }}^{1 / 2}=1 / 2 \sqrt{3 / 2 \nu} . \tag{35}
\end{align*}
$$

With the wave functions (32) and (33), the radial function $u_{0}$ is a gaussian function

$$
\begin{equation*}
\mathrm{u}_{0}(\mathrm{r})=4 \sqrt{2} \delta^{-3}\left(\pi^{-1} \lambda^{9} \nu^{6}\right)^{1 / 4} \mathrm{e}^{-\lambda r^{2} / 2} \tag{36}
\end{equation*}
$$

where $\delta=\nu+\lambda / 2$. To calculate $\mathrm{v}_{2}(\mathrm{r})$ from eq. (31) it is convenient to write

$$
\begin{align*}
& \chi_{0}(1,3) \chi_{0}(2,4)= \\
& -1 / 2\left[\chi_{0}(1,4) \chi_{0}(3,2)+\sum_{m}(-1)^{1+m} \chi_{1}^{m}(1,4) \chi_{1}^{-m}(3,2)\right] \tag{37}
\end{align*}
$$

since we are interested in the tensor force in the nucleon pairs 1,4 and 2,3 . Using the relation

$$
\begin{equation*}
\mathrm{S}_{12}(\hat{\mathrm{r}}) \chi_{1}^{\sigma}=4 \sqrt{2 \pi} \sum_{\sigma^{\prime} M}\left(1 \sigma^{\prime} 2 \mathrm{M} \mid 1 \sigma\right) \mathrm{Y}_{2}^{\mathrm{M}}(\hat{\mathrm{r}}) \chi_{1}^{\sigma^{\prime}} \tag{38}
\end{equation*}
$$

and eqs. (32) and (33) we obtain

$$
\begin{gather*}
\mathrm{v}_{2}(\mathrm{r})=2^{7}\left(\lambda^{3} / \pi\right)^{3 / 4}(\nu / \delta)^{3 / 2} \exp \left[-(\nu+\lambda) \mathrm{r}^{2}\right] \\
\int_{0}^{\infty} \mathrm{j}_{2}(2 \mathrm{i} \delta \mathrm{r} \mathrm{x}) \exp \left(-\delta \mathrm{x}^{2}\right) \mathrm{V}_{\mathrm{T}}(\mathrm{x}) \mathrm{x}^{2} \mathrm{~d} \mathrm{x} . \tag{39}
\end{gather*}
$$

Finally doing the integrations over $r$ in eq. (25) gives

$$
\begin{gather*}
\mathrm{D}_{2}=(8 / 15)\left(\mathrm{B}_{\alpha}-2 \mathrm{~B}_{\mathrm{d}}\right)^{-1}\left(\lambda^{3} / \pi\right)^{1 / 2}[\delta /(\nu+\lambda)]^{\tau / 2}  \tag{40}\\
\int_{0}^{\infty} \mathrm{V}_{\mathrm{T}}(\mathrm{x}) \exp \left[-\lambda \delta \mathrm{x}^{2} / 2(\nu+\lambda)\right] \mathrm{x}^{4} \mathrm{dx}
\end{gather*}
$$

Using the one-pion-exchange tensor potentital (OPEP)

$$
\begin{equation*}
\mathrm{V}_{\mathrm{T}}(\mathrm{r})=-\mathrm{C}_{\mathrm{T}} \mathrm{~h}_{2}(\mathrm{i} \mu \mathrm{r}) \tag{41}
\end{equation*}
$$

with $\mathrm{C}_{\mathrm{T}}=10.463 \mathrm{MeV}$ and $\mu=0.7 \mathrm{fm}^{-1}$ [20] we obtain $\mathrm{D}_{2}=-0.153 \mathrm{fm}^{2}$ for deuteron and $\alpha$ particle rms radius of 1.96 fm and 1.42 fm [21], respectively. The introduction of a cutoff factor [22], $1-\exp \left(-\mathrm{Ar}^{2}\right)$ where $\mathrm{A}=0.735 \mathrm{fm}^{-2}$, in the OPEP tensor potential increases $\mathrm{D}_{2}$ to $-0.117 \mathrm{fm}^{2}$. This change of $23 \%$ indicates that the parameter $\mathrm{D}_{2}$ depends on the behaviour of the tensor interaction at distances smaller than 2 fm . The sensitivity of $D_{2}$ to the tensor interaction at short distances is much stronger in $(d, \alpha)$ than in $(d, p),(d, t)$ or $\left(d,{ }^{3} \mathrm{He}\right)$ reactions. The values of $D_{2}$ become slightly larger when either the rms radius of the deuteron or the rms radius of the $\alpha$ particle are increased. For instance $D_{2}=-0.124 \mathrm{fm}^{2}$ for deuteron and $\alpha$ particle rms radii of 2.10 fm and 1.70 fm , respectively.

Although the model used to calculate $D_{2}$ is probably realistic the bound state wave functions are not adequate. In fact $D_{2}$ is very sensitive to the asymptotic region of large $r$. Thus we can expect that the calculated values of $\mathrm{D}_{2}$ are overestimated because they were obtained with gaussian functions. The same problem of overestimated values of $\mathrm{D}_{2}$ was also found in calculations of $\mathrm{D}_{2}$ for ${ }^{3} \mathrm{H}$ when using wave functions with incorrect asymptotic
behaviour [23]. Calculations based on the very simplified model for $\rho$ developed in ref. [5] give $-0.35<\mathrm{D}_{2}<-0.15 \mathrm{fm}^{2}$ [24]. This model has the unrealistic feature that the tensor interaction between clusters depends only on the coordinate $r$ but, on the other hand, the calculations were performed with wave functions $\mathrm{u}_{0}(\mathrm{r})$ with correct asymptotic behaviour.

## 5 - PERIPHERAL MODEL OF ( $\mathrm{d}, \alpha$ ) AND ( $\alpha, \mathrm{d}$ ) REACTIONS

To study the dependence of the cross section and of the analysing powers on the amplitudes $\mathrm{G}_{\mathrm{NLJ}}$ and also on the asymptotic D - to S -state ratio $\rho$ we use the peripheral model developed in refs. [5, 25]. The bound state wave functions of the transferred two nucleon cluster in the $\alpha$ particle and in the nucleus B are represented by their asymptotic forms for large $r$

$$
\begin{gather*}
\mathrm{u}_{\mathrm{L}^{\prime}}(\mathrm{r}) \simeq{N_{L^{\prime}} \mathrm{i}^{L^{\prime}} \mathrm{h}_{\mathrm{L}^{\prime}}(\mathrm{i} \alpha \mathrm{r}),}^{\phi_{\mathrm{NL}}(\mathrm{r}) \simeq \chi_{\mathrm{NL}} \mathrm{i}^{\mathrm{L}} \mathrm{~h}_{\mathrm{L}}(\mathrm{i} \beta \mathrm{r}) .} . \tag{42}
\end{gather*}
$$

Here $\beta$ is the wave number corresponding to the binding energy of the cluster x in B and $\chi_{\mathrm{NL}}$ are asymptotic normalization constants. For small recoil effects the $\tilde{\mathrm{B}}_{\mathrm{NLL}} \mathrm{l} \mathrm{\lambda}$, amplitudes can be approximated by

$$
\begin{align*}
& \tilde{\mathrm{B}}_{\mathrm{NLL}^{\prime}}^{\mathrm{L}} \simeq \sqrt{3} / 2 \sum_{\mathrm{MM}^{\prime}}(-1)^{1+\mathrm{M}^{\prime}}\left(\mathrm{LML} L^{\prime}-\mathrm{M}^{\prime} \mid l \lambda\right) \\
& \int d^{3} R \int d^{3} r \chi_{d}^{(-)}{ }^{*}\left(\mathbf{k}_{\mathrm{d}},\left(\mathrm{~m}_{\mathrm{A}} / \mathrm{m}_{\mathrm{B}}\right) \mathbf{R}\right) \phi_{\mathrm{NL}}(|\mathbf{R}-\mathrm{ar}|)  \tag{44}\\
& Y_{L}^{M^{*}}(\mathbf{R}-\hat{a} \mathbf{r}) v_{L^{\prime}}(\mathbf{r}) Y_{L^{\prime}}^{M^{\prime}}(\hat{r}) \chi_{\alpha}^{(+)}\left(\boldsymbol{k}_{\alpha}, \mathbf{R}\right) .
\end{align*}
$$

The value of the parameter a depends on the particular assumptions made in the derivation of eq. (44). For instance if we choose $\mathbf{R}$ as the average of the arguments of the two distorted waves [26] then $\mathrm{a}=3 / 4$. In the usual form of the non-recoil approximation [27] for heavy ion transfer reactions $\mathrm{a}=1$.
F. D. Santos et al. - D-state and nuclear structure effects in ( $d, \alpha$ ) reactions

With the bound state wave functions (42) and (43) the $r$ integration in eq. (44) can be performed analytically. In fact the formula A. 46 of ref. [14] gives

$$
\begin{gather*}
\int \mathrm{d}^{3} \mathrm{ri}^{\mathrm{L}} \mathrm{~h}_{\mathrm{L}}(\mathrm{i} \beta|\mathbf{R}-\mathbf{r}|) \mathrm{Y}_{\mathrm{L}}^{\mathrm{M}}{ }^{*}(\mathbf{R} \hat{-} \mathbf{r})\left(\nabla^{2}-\alpha^{2}\right) \mathrm{i}^{\mathrm{L}^{\prime}} \mathrm{h}_{\mathrm{L}^{\prime}}(\mathrm{i} \alpha \mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathbf{r}}) \\
=\sqrt{4 \pi} \hat{\mathrm{~L}}^{\prime}\left(\mathrm{L}^{\prime} 0 l 0 \mid \mathrm{L} 0\right)(-1)^{\mathrm{L}^{\prime}+\mathrm{M}^{\prime}}\left(\mathrm{L} \mathrm{ML}^{\prime}-\mathrm{M}^{\prime} \mid l \lambda\right)  \tag{45}\\
\left(\beta^{\mathrm{L}^{\prime}} / \alpha^{\mathrm{L}^{\prime}+1}\right) \mathrm{i}^{l} \mathrm{~h}_{l}(\mathrm{i} \beta \mathrm{R}) \mathrm{Y}_{l}^{\lambda^{*}}(\hat{\mathbf{R}})
\end{gather*}
$$

Therefore using eqs. (42), (43) and (45) we obtain

$$
\begin{align*}
& \sum_{\mathrm{MM}^{\prime}}^{\sum}(-1)^{1+\mathrm{M}^{\prime}}\left(\mathrm{LML} \mathrm{~L}^{\prime}-\mathrm{M}^{\prime} \mid l \lambda\right) \\
& \quad \int \mathrm{d}^{3} \mathrm{r} \phi_{\mathrm{NL}}(|\mathbf{R}-\mathrm{ar}|) \mathrm{Y}_{\mathrm{L}}^{\mathrm{M}}\left(\mathrm{R} \hat{-\mathrm{a} \mathbf{r}) \mathrm{v}_{\mathrm{L}^{\prime}}(\mathrm{r}) \mathrm{Y}_{\mathrm{L}^{\prime}}^{\mathrm{M}^{\prime}}(\hat{\mathbf{r}})=}\right.  \tag{46}\\
& -\frac{\hbar^{2}}{2 \mathrm{M} \alpha} \chi_{\mathrm{NL}} n_{\mathrm{L}^{\prime}} \sqrt{4 \pi} \hat{\mathrm{~L}}^{\prime}\left(\mathrm{L}^{\prime} 0 l 0 \mid \mathrm{L} 0\right)\left(\frac{\mathrm{a} \beta}{\alpha}\right)^{\mathrm{L}^{\prime}} \mathrm{i}^{l} \mathrm{~h}_{l}(\mathrm{i} \beta \mathrm{R}) \mathrm{Y}_{l}^{\lambda^{*}}(\hat{\mathbf{R}})
\end{align*}
$$

The neglect of the recoil induced by the transfer implies that only normal parity values of $l$ are allowed

$$
\begin{equation*}
l+\mathrm{L}+\mathrm{L}^{\prime}=\text { even } \tag{47}
\end{equation*}
$$

The substitution of eq. (46) into eq. (44) and the use of plane waves to represent the scattering states gives

$$
\begin{equation*}
\tilde{\mathrm{B}}_{\mathrm{NLLL}}{ }^{\prime}=\mathrm{I}_{l}(\mathrm{Q}) \mathrm{Y}_{l}^{\lambda^{*}}(\hat{\mathrm{Q}}) \hat{\mathrm{L}}^{\prime}\left(\mathrm{L}^{\prime} 0 l 0 \mid \mathrm{L} 0\right)(\mathrm{a} \beta / \alpha)^{\mathrm{L}^{\prime}} \chi_{\mathrm{NL}} \chi_{\mathrm{L}^{\prime}} \tag{48}
\end{equation*}
$$

Here

$$
\begin{equation*}
\mathbf{Q}=\mathbf{k}_{\alpha}-\left(\mathrm{m}_{\mathrm{A}} / \mathrm{m}_{\mathrm{B}}\right) \mathbf{k}_{\mathrm{d}} \tag{49}
\end{equation*}
$$

is the momentum transfer in the reaction and

$$
\begin{equation*}
\mathrm{I}_{l}(\mathrm{Q})=2 \sqrt{3} \pi\left(\hbar^{2} / \mathrm{M} \alpha\right)(-1)^{l+1} \int \mathrm{~h}_{l}(\mathrm{i} \beta \mathrm{R}) \mathrm{j}_{l}(\mathrm{QR}) \mathrm{R}^{2} \mathrm{dR} \tag{50}
\end{equation*}
$$

Finally the combination of eqs. (13) and (48) yield

$$
\begin{equation*}
\mathrm{B}_{1 J}^{l \lambda}=\mathrm{U}_{l J} \mathrm{Y}_{l}^{\lambda^{*}}(\hat{\mathrm{Q}}), \tag{51}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{U}_{l J}=\mathrm{I}_{l}(\mathrm{Q}) \sum_{\mathrm{LL}} \mathrm{~S}_{\mathrm{LJ}} \hat{\mathrm{~L}}^{\prime}\left(\mathrm{L}^{\prime} 0 l 0 \mid \mathrm{L} 0\right) \mathrm{A}_{l 1 \mathrm{~J} 1}^{\mathrm{LL}^{\prime}} \pi_{\mathrm{L}^{\prime}}(\mathrm{a} \beta / \alpha)^{\mathrm{L}^{\prime}} \tag{52}
\end{equation*}
$$

The information on the $A+2$ nucleus is now entirely contained in the spectroscopic amplitude
$S_{L J}=\sum_{N} G_{N L J} n_{N L}=\sum_{N \eta} \delta_{J}(\eta) \mathcal{G}_{L 1 J}(\eta) c_{0 N L}(\eta) n_{N L}$.
Using eqs. (15) and (51) it is easily concluded that the cross section is an incoherent sum of the square of the amplitudes $\mathrm{U}_{l \mathrm{~J}}$ over $l$ and J

$$
\begin{equation*}
\mathrm{d} \sigma / \mathrm{d} \Omega \propto\left(2 \mathrm{~J}_{\mathrm{B}}+1\right) / 4 \pi \sum_{l J} \mathrm{U}_{l J}^{2} . \tag{54}
\end{equation*}
$$

It is also straightforward to obtain an expression for the analysing powers $T_{k q}$ as a function of $U_{l \mathrm{~J}}$. Since the dependence on the magnetic quantum number in $\mathrm{B}_{1 J}^{l \lambda}$ is now given by the spherical harmonic $Y_{l}^{\lambda}$ the summation over $\lambda$ and $\lambda^{\prime}$ in eq. (18) gives rise to a Clebsch-Gordan coefficient ( $l 0 l^{\prime} 0 \mid \mathrm{k} 0$ ) and implies that the $\mathrm{T}_{\mathrm{kq}}$ are proportional to $\mathrm{Y}_{\mathrm{k}}^{\mathrm{q}}(\hat{\mathrm{Q}})$. Furthermore there is a restriction in the values of k . In a given transition the allowed values of $L$ have all the same parity and $L^{\prime}$ is even. Therefore the selection rule (47) implies that all values of the total orbital angular momentum transfer $l$ have the same parity. In conclusion the analyzing powers with k odd vanish in the peripheral model. This is a general property of plane wave approximations [28]. For $\mathrm{k}=2$ eqs. (18) and (51) yield

$$
\begin{equation*}
\mathrm{T}_{2 \mathrm{q}}=-(8 \pi / 5)^{1 / 2} \mathrm{~A} \mathrm{Y}_{2}^{\mathrm{q}}(\hat{\mathrm{Q}}), \tag{55}
\end{equation*}
$$

with
$\mathrm{A}=(3 / 2)^{1 / 2}\left(\sum_{l J} \mathrm{U}_{l J}^{2}\right)^{-1} \sum_{l l^{\prime} \mathrm{J}} \hat{l} \hat{l}^{\prime}\left(l 0 l^{\prime} 0 \mid 20\right) \mathrm{W}\left(l 1 l^{\prime} 1 ; \mathrm{J} 2\right) \mathrm{U}_{l \mathrm{~J}} \mathrm{U}_{l^{\prime} \mathrm{J}}$.

## F. D. Santos et al. - D-state and nuclear structure effects in ( $d, \alpha$ ) reactions

Eq. (55) shows that in the peripheral model the angular dependence of the tensor analyzing powers is essentially determined by the spherical harmonics $\mathrm{Y}_{2}^{\mathrm{q}}(\hat{\mathrm{Q}})$. In the Madison convention coordinate system [16] where the z axis is along $\mathrm{k}_{\mathrm{d}}$ and the y axis is along $\mathbf{k}_{\mathrm{d}} \times \mathbf{k}_{\mathrm{p}}$

$$
\begin{align*}
& \mathrm{T}_{20}=-(1 / \sqrt{2}) \mathrm{A}\left(3 \cos ^{2} \gamma-1\right),  \tag{57a}\\
& \mathrm{T}_{21}=\sqrt{3} \mathrm{~A} \sin \gamma \cos \gamma  \tag{57b}\\
& \mathrm{~T}_{22}=-(\sqrt{3} / 2) \mathrm{A} \sin ^{2} \gamma . \tag{57c}
\end{align*}
$$

The angle

$$
\begin{equation*}
\gamma=\operatorname{arctg}\left\{\sin \Theta\left[\cos \theta-\left(\mathrm{m}_{\mathrm{A}} / \mathrm{m}_{\mathrm{B}}\right)\left(\mathrm{k}_{\mathrm{d}} / \mathrm{k}_{\alpha}\right)\right]^{-1}\right\} \tag{58}
\end{equation*}
$$

is the angle between $\mathbf{Q}$ and $\mathbf{k}_{\mathrm{d}}$ and $\theta$ is the scattering angle. The relations (57) acquire a particularly simple form when the tensor analyzing powers are expressed in a cartesian representation
$A_{x x}=-(1 / \sqrt{2})\left(T_{20}-\sqrt{6} T_{22}\right)=(\mathrm{A} / 2)(3 \cos 2 \gamma-1)$,
$A_{y y}=-(1 / \sqrt{2})\left(T_{20}+\sqrt{6} T_{22}\right)=A$,
$A_{z z}=-\left(A_{x x}+A_{y y}\right)=-(A / 2)(3 \cos 2 \gamma+1)$.
The most significant aspect of eq. (59) is that $A_{y y}$ is, to a good approximation, independent of $\theta$. This property of $A_{y y}$ is common to other reactions [25] and has a simple physical interpretation. The difference between the unpolarized cross section and a cross section for a spin orientation perpendicular to the reaction plane is insensitive to the scattering angle because the correlation between spin and deformation implies that the wave function of relative motion between clusters has spherical symmetry in the reaction plane. This spherical symmetry is broken for other spin orientations and as a result the tensor analyzing powers become dependent on $\Theta$. For instance the analyzing power $A_{x x}$ has a minimum of $-2 A$ at $\Theta=\operatorname{arc} \cos \left(m_{A} k_{d} / m_{B} k_{\alpha}\right)$ and is equal to A at $\Theta=0^{\circ}$ and $180^{\circ}$.

## 5.1 - Natural parity transitions

In natural parity transitions $\mathrm{L}=\mathrm{J}$. From eqs. (6) and (52) and with the help of tables of angular momentum coupling coefficients [12] we obtain

$$
\begin{equation*}
\mathrm{U}_{l \mathrm{~J}}=\delta_{l \mathrm{~J}}\left(n_{0} / \sqrt{3}\right) \mathrm{I}_{\mathrm{J}} \mathrm{~S}_{\mathrm{JJ}}\left[1+(\rho / \sqrt{2})(\mathrm{a} \beta / \alpha)^{2}\right] \tag{60}
\end{equation*}
$$

The differential cross section in a transition with a given J is

$$
\begin{equation*}
(\mathrm{d} \sigma / \mathrm{d} \Omega)_{\mathrm{J}} \propto\left(N_{0}^{2} / 12 \pi\right)\left\{\mathrm{I}_{\mathrm{J}} \mathrm{~S}_{\mathrm{JJ}}\left[1+(\rho / \sqrt{2})(\mathrm{a} \beta / \alpha)^{2}\right]\right\}^{2} . \tag{61}
\end{equation*}
$$

The fact that $\rho$ is negative implies that the $D$-state of the $\alpha$ particle decreases the cross section of ( $\mathrm{d}, \alpha$ ) and ( $\alpha, \mathrm{d}$ ) natural parity transitions. This effect is particularly noticeable in transitions with large $\beta$.

For the tensor analyzing powers the substitution of eq. (60) into eq. (56) gives $A=-1 / 2$ and therefore

$$
\begin{equation*}
\mathrm{A}_{\mathrm{yy}}=-1 / 2 \tag{62}
\end{equation*}
$$

This simple result is interesting to understand. $\mathrm{A}_{\mathrm{yy}}$ is equal to the polarization component [16]

$$
\begin{equation*}
\mathrm{p}_{\mathrm{yy}}=\left\langle 3 \mathrm{~s}_{\mathrm{y}}^{2}-2\right\rangle \tag{63}
\end{equation*}
$$

of the outgoing deuteron beam in a ( $\alpha, \overrightarrow{\mathrm{d}}$ ) reaction. In a peripheral reaction the vector $L$ is perpendicular to the reaction plane and therefore either parallel or antiparallel to the y axis. For $\mathrm{L}=\mathrm{J}$ and because $\mathbf{J}=\mathbf{L}+\mathbf{s}_{\mathbf{x}}$, the spin $\mathbf{s}_{\mathbf{x}}$ is either parallel or antiparallel to the z axis. This is also true for the outgoing deuteron because of the spin correlation between the spin one clusters in the $\alpha$ particle. Thus in natural parity transitions the ( $\alpha, \mathrm{d}$ ) reaction acts as a spin filter supressing the $\mathrm{m}_{\mathrm{z}}=0$ states. In a polarization state where $\left.\mathrm{m}_{\mathrm{z}}= \pm 1,<\mathrm{s}_{\mathrm{y}}^{2}\right\rangle=1 / 2$ and therefore from eq. (63) $\mathrm{p}_{\mathrm{yy}}=\mathrm{A}_{\mathrm{yy}}=-1 / 2$.

## F. D. SAntos et al. - D-state and nuclear structure effects in $(d, \alpha)$ reactions

## 5.2 - Unnatural parity transitions

In unnatural parity transitions for a fixed $J$ the orbital angular momentum of the transferred cluster can be $L=J-1$ and $\mathrm{L}=\mathrm{J}+1$. Again from eqs. (6) and (52) we obtain [12] for $\mathrm{L}=\mathrm{J}-1$

$$
\begin{align*}
\mathrm{U}_{\mathrm{J}-1, \mathrm{~J}}= & \left(\varkappa_{0} / \sqrt{3}\right) \mathrm{I}_{\mathrm{J}-1}\left[\mathrm{~S}_{\mathrm{J}-1, \mathrm{~J}}+(\rho / \sqrt{2})(2 \mathrm{~J}+1)^{-1}(\mathrm{a} \beta / \alpha)^{2}\right. \\
& \left.\left(3[\mathrm{~J}(\mathrm{~J}+1)]^{1 / 3} \mathrm{~S}_{\mathrm{J}+1, \mathrm{~J}}-(\mathrm{J}-1) \mathrm{S}_{\mathrm{J}-1, \mathrm{~J}}\right)\right] \tag{64}
\end{align*}
$$

and for $\mathrm{L}=\mathrm{J}+1$

$$
\begin{align*}
\mathrm{U}_{\mathrm{J}+1, \mathrm{~J}}= & \left(n_{0} / \sqrt{3}\right) \mathrm{I}_{\mathrm{J}+1}\left[\mathrm{~S}_{\mathrm{J}+1, \mathrm{~J}}+(\rho / \sqrt{2})(2 \mathrm{~J}+1)^{-1}(\mathrm{a} \beta / \alpha)^{2}\right. \\
& \left.\left(3[\mathrm{~J}(\mathrm{~J}+1)]^{1 / 2} \mathrm{~S}_{\mathrm{J}-1, \mathrm{~J}}-(\mathrm{J}+2) \mathrm{S}_{\mathrm{J}+1, \mathrm{~J}}\right)\right] \tag{65}
\end{align*}
$$

Given J, the differential cross section is

$$
\begin{equation*}
(\mathrm{d} \sigma / \mathrm{d} \Omega)_{\mathrm{J}} \propto(1 / 4 \pi)\left(\mathrm{U}_{\mathrm{J}-1, \mathrm{~J}}^{2}+\mathrm{U}_{\mathrm{J}+1, \mathrm{~J}}^{2}\right) . \tag{66}
\end{equation*}
$$

Notice that for $\rho=0$

$$
\begin{equation*}
(\mathrm{d} \sigma / \mathrm{d} \Omega)_{\mathrm{J}} \propto\left(X_{0}^{2} / 12 \pi\right)\left(\mathrm{I}_{\mathrm{J}-1}^{2} \mathrm{~S}_{\mathrm{J}-1, \mathrm{~J}}^{2}+\mathrm{I}_{\mathrm{J}+1}^{2} \mathrm{~S}_{\mathrm{J}+1, \mathrm{~J}}^{2}\right) \tag{67}
\end{equation*}
$$

is insentitive to the sign of the spectroscopic amplitures $\mathrm{S}_{\mathrm{L}, \mathrm{J}}$.
Eqs. (64-66) show that, because $\rho$ is negative, the D-state of the $\alpha$ particle has generally the effect of increasing the cross section of unnatural parity transitions. This is the case, for instance, of a pure $\mathrm{L}=\mathrm{J}-1$ transition and also of a pure $\mathrm{L}=\mathrm{J}+1$ transition. The opposite effect of the D-state in natural and unnatural parity transitions introduces in the cross section a J-dependence which qualitatively is in agreement with that observed in the ${ }^{208} \mathrm{~Pb}(\alpha, \mathrm{~d}){ }^{210} \mathrm{Bi}$ reaction feeding members of the $\left\{\mathrm{h}_{9 / 2}, \mathrm{~g}_{9 / 2}\right\}$ multiplet [10].

We now consider the tensor analysing powers in unnatural parity transitions. Eqs. (56) and (59b) give

$$
\begin{equation*}
A_{y y}=A=\frac{(J+2) x^{2}-6[J(J+1)]^{1 / 2} x+J-1}{2(2 J+1)\left(1+x^{2}\right)} \tag{68}
\end{equation*}
$$

F. D. Santos et al. - D-state and nuclear structure effects in $(d, \alpha)$ reactions with

$$
\begin{equation*}
\mathrm{x}=\mathrm{U}_{\mathrm{J}+1, \mathrm{~J}} / \mathrm{U}_{\mathrm{J}-1, \mathrm{~J}} . \tag{69}
\end{equation*}
$$

Thus $\mathrm{A}_{\mathrm{yy}}$ varies from a minimum value of $-1 / 2$ for $\mathrm{x}=[\mathrm{J} /(\mathrm{J}+1)]^{1 / 2}$ to a maximum value of 1 for $\mathrm{x}=-[(\mathrm{J}+1) / \mathrm{J}]^{1 / 2}$.

In the absence of D-state effects $\rho=0$ and

$$
\begin{equation*}
\mathrm{x}=\mathrm{K}_{\mathrm{J}} \mathrm{~S}_{\mathrm{J}+1, \mathrm{~J}} / \mathrm{S}_{\mathrm{J}-1, \mathrm{~J}} \tag{70}
\end{equation*}
$$

where $K_{J}=I_{J+1} / I_{J-1}$ is a positive quantity due to the form of the integrals (50). Eqs. (55) and (68) show that the $T_{2 q}$ have a strong dependence on the spectroscopic amplitudes $\mathrm{S}_{\mathrm{LJ}}$. Unlike the cross section they depend on the relative sign of $S_{J-1, J}$ and $\mathrm{S}_{\mathrm{J}+1, \mathrm{~J}}$. Fig. 2 shows the values of

$$
\begin{equation*}
\left(\mathrm{A}_{\mathrm{yy}}\right)_{\mathrm{J}}=(\mathrm{J}-1) /[2(2 \mathrm{~J}+1)] \tag{71}
\end{equation*}
$$

for a pure $\mathrm{L}=\mathrm{J}-1$ transition $(\mathrm{x}=0)$ and

$$
\begin{equation*}
\left(\mathrm{A}_{\mathrm{yy}}\right)_{\mathrm{J}}=(\mathrm{J}+2) /[2(2 \mathrm{~J}+1)] \tag{72}
\end{equation*}
$$

for a pure $L=J+1$ transition $(x=\infty)$. Since $K_{J}>0, x>0$ when $S_{J+1, J}$ and $S_{J-1, J}$ have the same sign and $x<0$ when $\mathrm{S}_{\mathrm{J}+1, \mathrm{~J}}$ and $\mathrm{S}_{\mathrm{J}-1, \mathrm{~J}}$ have opposite signs. The quantity x is a double valued function of $A_{y y} \cdot x<0$ for $\left(A_{y y}\right)_{J}>(J+2) /[2(2 J+1)]$, $\mathrm{x}>0$ for $\left(\mathrm{A}_{\mathrm{yy}}\right)_{\mathrm{J}}<(\mathrm{J}-1) /[2(2 \mathrm{~J}+1)]$ and x is either positive or negative for $(\mathrm{J}-1) /[2(2 \mathrm{~J}+1)]<\left(\mathrm{A}_{\mathrm{yy}}\right)_{\mathrm{J}}<(\mathrm{J}+2) /[2(2 \mathrm{~J}+1)]$ as shown in Fig. 2.

In the presence of $D$-state effects $\rho \neq 0$ and for a pure $\mathrm{L}=\mathrm{J}-1$ transition

$$
\begin{equation*}
\mathrm{x}=\frac{\mathrm{K}_{\mathrm{J}}}{3 \rho \mathrm{~b}} \frac{3 \mathrm{~J}+1-\rho \mathrm{b}(\mathrm{~J}+2)}{[\mathrm{J}(\mathrm{~J}+1)]^{1 / 2}} \tag{73}
\end{equation*}
$$

where $\mathrm{b}=(\mathrm{a} \beta \alpha)^{2} / \sqrt{2}$. In a pure $\mathrm{L}=\mathrm{J}+1$ transition

$$
\begin{equation*}
\mathrm{x}=3 \rho \mathrm{~b} \mathrm{~K}_{\mathrm{J}} \frac{[\mathrm{~J}(\mathrm{~J}+1)]^{1 / 2}}{2 \mathrm{~J}+1-\rho \mathrm{b}(\mathrm{~J}-1)} . \tag{74}
\end{equation*}
$$

F. D. Santos et al. -D-state and nuclear structure effects in $(d, \alpha)$ reactions

In both cases $\mathrm{x}<0$. Therefore the effect of the D-state is to increase $\mathrm{A}_{\mathrm{yy}}$ relative to the values given by eqs. (71) and (72). The substitution of eqs. (73) and (74) into eq. (68) shows that the $\alpha$ particle D -state effect is relatively larger in $\mathrm{L}=\mathrm{J}-1$ than in $\mathrm{L}=\mathrm{J}+1$ transitions. This result is important to select transitions where the extraction of $\rho$ from $T_{2 q}$ experimental data is favoured.

Fig. 2 - The tensor analyzing power $\mathrm{A}_{\mathrm{yy}}$ of ( $\mathrm{d}, \alpha$ ) reactions to unnatural parity states as a function of the total angular momentum transfer J. The open and full points correspond to pure $\mathrm{L}=\mathrm{J}-1$ and pure $\mathrm{L}=\mathrm{J}+1$ transitions, respectively. For each J, $\mathrm{A}_{\mathrm{yy}}$ is given by eq. (68) and varies with x from $-1 / 2$ to 1 . For $\mathrm{J}=1$ we have represented in a loop the values taken by $\mathrm{A}_{\mathrm{yy}}$ as function of x .

In an unnatural parity transition with only one pair of values for $\mathrm{J}, \mathrm{L}$ the measurement of the $\mathrm{T}_{2 q}$ yields a unique value for x that can be used to estimate $\rho$. Knowing $\rho$ it becomes possible to determine the amplitudes $\mathrm{S}_{\mathrm{J}+1, \mathrm{~J}}$ and $\mathrm{S}_{\mathrm{J}-1, \mathrm{~J}}$ in transitions with L mixing. These amplitudes can then be compared with those obtained from shell model calculations.

## 6 - CONCLUSIONS

A general discussion of the angular momentum structure of the transition amplitude in $(\alpha, \mathrm{d})$ and ( $\mathrm{d}, \alpha$ ) reactions is presented. Particular emphasis is given to the analysis of contributions from the D-state components of the $\alpha$ particle wave function. The parameter $\mathrm{D}_{2}$ is estimated using a perturbative treatment to first order in the tensor interaction and gaussian wave functions to represent the deuteron and $\alpha$-particle bound state wave functions. These calculations show that $\mathrm{D}_{2}$ in ( $\mathrm{d}, \alpha$ ) reactions is sensitive to the form of the nucleon-nucleon tensor interaction at distances smaller than 2 fm . Further calculations of $\mathrm{D}_{2}$ using more realistic wave functions with correct asymptotic behaviour are required.

The dependence of the cross section and of the tensor analysing powers on the asymptotic D - to S -state ratio $\rho$ and on the spectroscopic amplitudes $\mathrm{S}_{\mathrm{LJ}}$ is discussed using a plane wave peripheral model. The tensor analyzing power $\mathrm{A}_{\mathrm{yy}}$ is particularly interesting because it is independent of angle and its value is a simple function of $\rho$ and $S_{\mathrm{LJ}}$. The present analysis indicates that the determination of $\rho$ from $T_{2 q}$ data is specially favoured in unnatural parity transitions involving only the orbital angular momentum $\mathrm{L}=\mathrm{J}-1$. These occur in ( $\mathrm{d}, \alpha$ ) reactions on closed shell target nuclei leading to outstretched nuclear configurations with $\mathrm{J}=\mathrm{L}+1$.

With the peripheral model it is possible to identify the main features of nuclear structure and D-state effects in the cross section and $\mathrm{T}_{2 \mathrm{q}}$. However the model cannot be applied to the description of $\mathrm{iT}_{11}$ and furthermore it cannot be used in a quantitative analysis of the data. For instance the experimental $\mathrm{A}_{\mathrm{yy}}$ angular distributions oscillate around a certain mean value [5] that varies from transition to transition. This mean value can be
F. D. Santos et al. - D-state and nuclear structure effects in (d, $\alpha$ ) reactions
interpreted with the peripheral model but to reproduce the oscillatory behaviour it is necessary to perform a DWBA calculation including a spin-orbit interaction in the deuteron channel [7, 8]. An analysis of recent $\mathrm{T}_{2 q}$ data in ( $\mathrm{d} \alpha$ ) reactions with full finite range DWBA calculations is in progress and shall be presented elsewhere.

We are thankful to W.J. Thompson for illuminating discussions. One of us (FDS ) would like to thank the hospitality of the Department of Physics and Astronomy of the University of North Carolina where part of this work was performed.
